

Fertilization F.A.Q- Best Lawn

Nitrogen, Phosphorus, and Potassium (NPP) are essential for your lawn!.

Maintaining your lawn is the most important aspect of having a beautiful, green lawn. Fertilizing will ensure your grass is receiving all of the elements to grow healthy. Finding the right fertilizer and the right time to fertilize can be difficult at times.

Fertilizing a lawn regularly will give it a healthy green color as well as help prevent disease and weed problems. If a lawn is well fed and growing rapidly, disease spots on the grass blades are mowed off before they become visible. A thick lawn will prevent weeds from getting started. Fertilizer makes the seed germinate faster, and get started out of the ground. After the grass has a good start fertilizer will make the grass get thicker send off Rhizomes, Stolons or Tillers all making the grass thicker and healthier.

Your lawn actually needs 16 different elements to survive, but most of them are already provided to the lawn from the soil and natural surroundings. There are three elements, however, that needed to be added to your lawn in the form of fertilizer – nitrogen, phosphorus, and potassium (NPP).
